Conference system.

The present invention relates to a distributed object-based computer system in which sharable objects are split into client and server components (see Figure 7). Each client object contains a reference to the associated server object component. By copying client object components to other users, these other users obtain access to the relevant server-object component. This feature is described in the context of a distributed conferencing system.

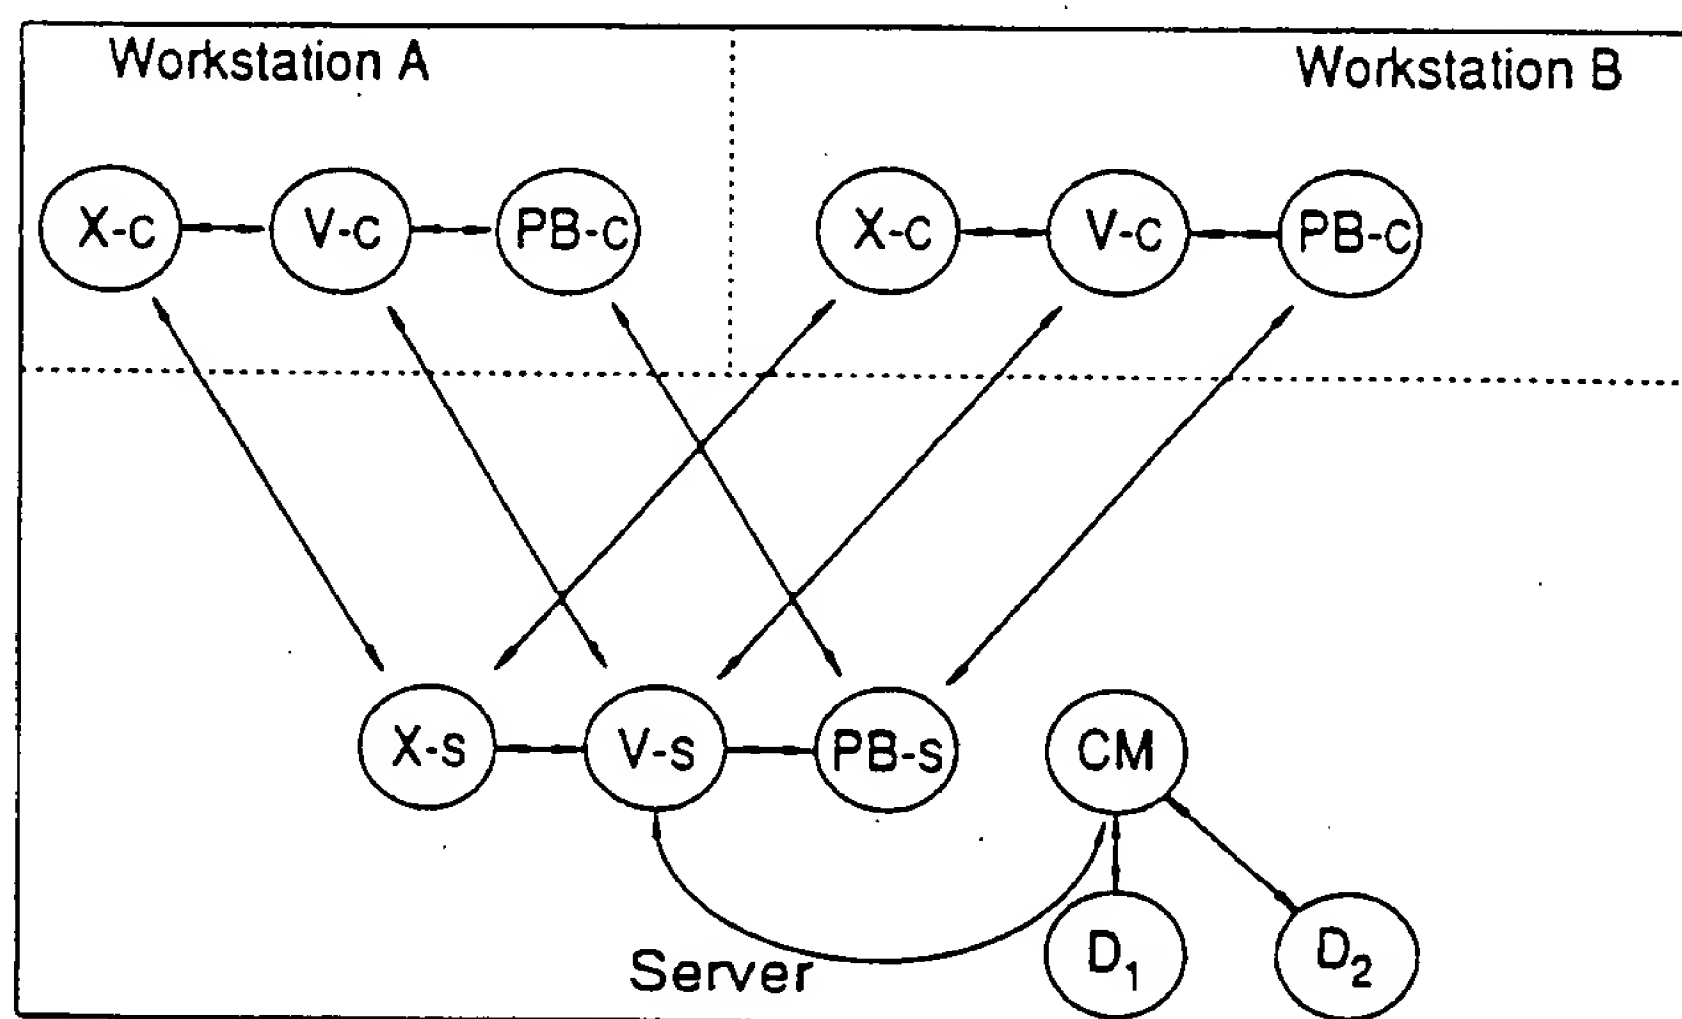

FIG 7

EP 0 497 022 A1

The present invention relates to a distributed computer system and relates particularly, but not exclusively, to a multimedia distributed object-based conference system.

The object-based approach to system development is becoming well-established. The basic idea is to program the system in terms of software objects, each having its own data and methods for operating on the data. Objects intercommunicate by means of messages. An advantage in encapsulating data and methods in this way is that the resulting system is relatively easy to maintain and develop. An example is NewWave Mail (produced and sold by Hewlett-Packard) which is an object-based electronic mail applications program in which messages and message components, such as text, distribution lists, etc. are treated as objects.

An object can be regarded as a discrete entity which can individually be moved, copied, destroyed, etc. An object is initially some data stored on disc or other medium. If object management software wishes to pass a message to it, one or more processes will be initiated which read the data as part of initialization. If an object is fully defined by its data and has no processes associated with it, it is said to be "inactive". If an object has one or more processes associated with it and is defined by the state of that process or processes and data then it is said to be "active".

A distributed object based system is one in which several workstations are interconnected over a network and messages between objects of the system can be sent over the network. Objects themselves may also be transmissible over the network. A network may comprise several interconnected intelligent workstations or a central computer connected to several terminals (workstations) or several interconnected server machines with intelligent workstations connected to each server, or a mixture of these possibilities. The term "workstation" is intended to be applicable to all of these possibilities.

In a distributed object based system there are benefits in splitting sharable semantic and presentation parts so as to enable more than one user to access the semantic part of a shared object. For example, in the context of a distributed conferencing system a whiteboard object would have a semantic part defining the state of the object and a presentation part for defining the appearance of the object to be displayed to a user and for enabling the user to make input. Several users may have access to a presentation part for viewing the whiteboard object so that they can each make contributions in a manner similar to a group of people clustered around a real whiteboard.

The workstations may be arranged in a client-server arrangement with semantic object parts stored on server machines and presentation object parts stored on client machines. Alternatively, semantic object parts may be distributed around user machines on a network of intelligent workstations.

According to the present invention we provide an object based distributed computer system comprising a network of workstations and means for transmitting objects between workstations characterized by objects including a first object type for storing data and a second object type for presenting data to a user, wherein objects of the second type reference an associated object of the first type to enable a plurality of users of workstations to access data of the object of the first type, comprising means for transmitting an object of the second type between workstations thereby to create a reference to the associated object of the first type for each workstation receiving an object of the second type.

The present invention provides an effective way of enabling further users to have access to a semantic object part, either for the purpose of autonomous working or for the purpose of participating in a joint activity.

In the embodiment to be described, the system comprises means for copying an object of the second type between workstations. In that embodiment transmitted objects of the second type include an identifier for the associated object of the first type.

The system according to the present invention may be in the form of a conferencing system comprising means enabling users of the workstations to participate in a meeting over the network wherein objects of the first type store meeting data and objects of the second type are for presenting meeting data. The invention also provides a method of convening a meeting using such a system comprising transmitting an object of the second type between workstations thereby to create a reference to the associated object of the first type for each workstation receiving an object of the second type.

It is believed that poor communications are a major cause of the poor performance of distributed teams of people working on a given project. The present invention advantageously provides an improved conference system for facilitating distributed meetings.

A particular embodiment of the present invention will now be described, by way of example, with reference to the accompanying drawings in which:

Figure 1 is a diagram of a distributed system according to the present invention;

Figure 2 shows the major components of a server and workstation of the system;

Figure 3 shows a voice and data network structure;

Figure 4 shows video facilities for a client workstation;

Figure 5 shows a video network structure;

Figure 6 illustrates the main objects in the system;

Figure 7 illustrates the functionally split nature of the objects in the system;

5 Figure 8 shows the major components of the system infrastructure;

Figure 9 shows a typical Venue;

Figure 10 shows a CoMedian directory;

Figures 11 - 14 illustrate message sequences for system operations;

Figures 15 - 27 show screens during a typical user session.

10 The main components of a multi-media distributed object-based conferencing system according to the invention will first be described.

Referring to Figure 1, a multimedia distributed object-based conference system according to the present invention is indicated at 10. The system 10 comprises servers S connected over a network 12. The network 12 may be a wide area network (WAN) or a local area network (LAN) or a metropolitan area network (MAN). Client workstations C are connected to each of the servers S. Each site requires a server S.

15 Servers S communicate with each other by opening virtual circuits between pairs of servers. Although in principle, client workstations C could communicate directly with each other, this creates practical problems and therefore each client workstation C has only one virtual channel open to its local server S to enable client workstations to communicate with each other via servers S.

20 Referring to Figure 2, each server S comprises:

hardware 14, such as an HP9000 300 HP-UX computer (HP is a trade mark of Hewlett Packard Company);

operating system software 16, such as HP-UX software;

25 Remote Object Access Manager (ROAM) software 18 for managing communications with client workstations C connected to the server S and other servers on the network;

COM software 20 providing object management facilities;

server objects 21 which are objects to be shared between users and which correspond to the semantic object parts mentioned in the introduction.

Each client workstation C comprises:

30 hardware 22, such as an IBM-AT compatible PC;

operating system software 24, such as DOS software;

windowing software 26, such as MS Windows applications software;

an object management facility (OMF) 28, such as a Standard NewWave OMF. (Newwave is a trade mark of Hewlett-Packard Company used for a family of applications software);

35 objects software 30, such as NewWave objects and specialized client objects 32 and a ROAM object 34 for handling communication with objects on other computers. The client objects 32 correspond to the presentation object parts mentioned in the introduction.

40 The user of a client workstation C therefore has a windowed user interface within which to manipulate objects of the system and can cause objects to be transmitted over the network 12 via the associated server S.

The system 10 provides multimedia facilities to users. For example, each client workstation C may have voice and/or video communication facilities as well as data communication facilities.

A possible voice and data network structure 40 is shown in Figure 3. In each of two sites designated A and B, a networked PC server 42 is connected to the local PABX. The PC server 42 contains one or more multi-port telephone interface cards (such as the VBX-300 card made by Natural Microsystems Inc.). The PABX is controlled by the PC server 42 and users can use their existing standard desk telephones 44 which are connected to the local PABX and conveniently located near their client workstations C.

Each of the sites A and B comprises a LAN and a LAN/WAN bridge interconnecting the LAN with a WAN.

50 In use, the PC server 42 receives commands from servers S to set up, maintain and close down telephone conference calls. To the PABX, the PC server 42 appears as a normal telephone user and can therefore dial other users adding them in to conference calls using DTMF.

In order to conduct conferences over a wider area, PC servers 42a and 42b on respective sites A and B connect to each other over the public switched telephone network (PSTN) and add in their own local users to the conference.

55 Referring to Figure 4, each client workstation C with video facilities has a video camera 46, two or more VHF TV receivers 48, a microphone 50, a preamplifier 51 and a VHF modulator 52.

Furthermore, the client workstations C may be fitted with video cards to enable a user to view video in

windows.

A possible video network is shown in Figure 5. The video network is based on a central video switch 54 connected using a star topology to client workstations C. Video signals are modulated on to VHF carriers and transmitted over standard analogue cabling 56. The video switch 54 is a conventional cable television switch. Several such switches can be cascaded in a bar arrangement for large systems.

For long distance video communications, a device 58 for compressing and decompressing video signals (a "codec") may be used and the signals are transmitted using ISDN telephone lines.

The architecture of the object-based system 10 will now be described.

With reference to Figure 6, the structure of one user's portion of the system is represented. The functions of the objects are as follows:

a Venue object (V) is an electronic meeting place allowing control over media channels and providing a location for storing shared objects. A user may have several Venue objects:

a Phone Booth object (PB) controls the creation of Venue objects and oversees the setting up, maintenance and closing down of conferences. The PB comprises a processor for handling incoming and outgoing calls;

a Connection Manager object (CM) controls driver components ($D_1 \dots D_n$) which handle media connections for the system 10;

a Directory object (D) which provides a list of potential meeting participants.

Object X represents another system object for performing a specific meeting-related function, eg. a whiteboard function.

Figure 6 is a conceptual representation of the system 10 and the arrows represent inter-object communication. In the embodiment being described, the system comprises client workstations C and servers S and most of the objects referred to in Figure 6 are functionally-split into a server component and one or more client components as indicated in Figure 7.

The server objects handle the centralized and distribution - oriented aspects whereas the client objects handle the presentation aspects. Hence shared applications can be written with one server object connected to a plurality of client objects on different client workstations.

In Figure 7, PB-s means a Phone Booth server object and PB-c means a Phone Booth client object, and so on.

In this embodiment, the client objects are implemented as NewWave objects ie. several new classes of NewWave objects have been added: Venue objects, ROAM objects, Whiteboard objects, Phone Booth objects. Thus the semantic part of these functionally split objects runs on an HP-UX server and the user interface runs on MS-DOS NewWave client workstations.

The client workstations are each running an object-based system of the type described in European Patent Application No.339220A, the description of which is incorporated herein as Appendix A. Appendices A-D mentioned in attached Appendix A are not attached as part of this application but are incorporated herein by reference. Appendix A describes how objects are linked together by parent-child links and how objects can be copied. During a copy operation, the container of the object to be copied sends a message to the OMF28 asking the OMF28 to copy the relevant object and identifying the container object which is to receive the copy object.

The OMF28 performs the copy function and then sends a message to the target container object instructing it to insert the copy object as one of its child objects.

Mailing an object involves serialising the object, transmitting it to its destination and deserialising it. Serialising an object involves converting it to files, say DOS files, containing the data of the object and information about its properties and its child objects.

Server objects are not linked by parent-child links in the manner in which client objects are so linked. All client objects contain a reference to their associated server object. Figure 8 shows the form of data item 60 used to name objects. The data item 60 is an eight-byte array following the convention used for Internet Protocol (IP) addresses. The first 64 bits is a machine identifier M I/D comprising a 32 bit server IP address and a 32 bit machine IP address. For a server object the server IP address and the machine IP address will be the same whereas for a client object these will be different. If there is only one domain per machine, the domain identifier D I/D is zero. The object identifier O I/D comprises a 32 bit generation count and a 16 bit tag. The 16 bit tag uniquely identifies the object within the relevant storage domain. Since tags are reusable when an object is deleted a generation count is used to ensure that each object is uniquely-named in time. The generation count is simply the time in seconds.

When a client object is closed (inactive) it appears as an icon on a user's screen. The user opens the object by clicking on the icon. Opening a client object causes it to send a message to its associated server object informing the server object that the client object is now active i.e. a Here Am I message. Until then,

the server object is unaware of the existence of the client object. In other words, links between client and server objects are non-persistent and 'weak' i.e. the existence of a server object does not guarantee the existence of a corresponding client object and vice-versa. Server objects only store the identities of corresponding client objects which are currently active. Opening a client object means that a user can view the state of the object and can make input to it. The client object regularly updates, and is updated by, the server object.

Figure 9 depicts the components involved in a typical active server object which is associated with client objects on two different client workstations C₁ and C₂. Each object is given a unique object identifier comprising components identifying the relevant client-server machine, the relevant storage domain and a number for the particular object. On the client side, the system has an object management facility (OMF) 60 for keeping a record of what objects are presently on the particular client workstation and which is involved in object creation and deletion, object naming, object activation and deactivation and inter-object message routing. This is a standard NewWave OMF. There is a client object manager library (COMLIB-C) 61 statically linked to each client object CO providing access to the functionality of a ROAM client object 62. In other words, the COMLIB-C 61 has been added to standard NewWave objects to form the client objects for functionally split objects. Communication through the COMLIB-C 61 is network transparent, i.e. objects only need to know the object identifiers of other objects, not their locations.

On the server side there is a primitive object management facility (COM-S) 63 providing file management and object naming and message sending facilities in conjunction with the operating system software 64. A server object manager library (COMLIB-S) 65 is statically linked to each server object SO enabling access to the functionality of the object management facility 63 and a ROAM server object 66.

When client object CO₁ wishes to send a message to the corresponding server object SO, the ROAM client object 62 passes the message to the ROAM server object 66 which passes the message on to the server object SO. Messages from the server object SO to client objects are sent in the reverse manner. If a message is to be sent between objects on the same server the COMLIB-S 65 sends it directly without involving the ROAM server object 66. Messages are also sent between servers via the ROAM server object 66 and, in this way, communication between client workstations connected to different server machines is possible.

The functionality of certain objects in the system will now be described. The term "click" will be used in this specification to denote a selection made by the user of a workstation using an input device, such as a mouse. The term "drag" will denote moving the input device whilst such a selection is made so as to "drag" an item across the screen.

The Venue provides an electronic meeting room, inside of which person-to-person calls, group meetings and presentations to large groups can be held.

Venues provide a binding between the people involved in a meeting, the data which they are sharing, and the media channels connecting them. They are scalable from just two people up to many people, the exact number is subject to technical constraints. This allows a meeting to start off as a simple phone call between two people, build up as experts are brought in, to become a full group discussion without having to decide to move to a different object because the nature of the meeting has changed.

The Venue is a shared object and therefore exists on a server machine. The client workstations have Venue client objects which provide an interface to the Venue server objects running on the corresponding server. There may be many Venue client objects on different client workstations for a particular Venue server object.

Figure 10 shows the appearance of a Venue to a user. The Venue is being viewed in a window 70 having a title bar 72 and a menu bar 74. At the top is a participants' area 76 where the people in the Venue can be seen and where their media channels can be controlled. Beneath that is a shared area 78 where objects for use in the meeting are stored.

The participants in a Venue are displayed side by side, with each participant being represented by a still bitmap 80, a name 82 accompanied by an indication of whether that user is present in the meeting or absent and status banner 84 indicating that an absent user has been invited to the meeting, and a row of media control buttons 86. The bitmap 80 may be replaced by a motion video window when video in windows is available and the video channel is in use.

Beneath the participants' area are three media buttons 86 for telephone, video and data and each one can be in one of four states. The states are:

Button Appearance	Meaning
No button	This person does not have this media channel available.
White, unhighlighted	The media channel is available, but not chosen for use.
Black	The media channel has been selected, but is inactive because the person is not present in the Venue or the connection has not been completed yet.
Red	The media channel is being used.

The lower portion of the Venue is taken up by the shared object area 78. This acts as a shared folder, storing objects on the server and making them accessible to all users of the Venue. Inactive objects are represented by an icon such as icon 88 in Figure 10. Objects in the shared object area 78 may be client objects e.g. Whiteboard client objects, or may be standard NewWave objects. It is possible to move objects into and out of the shared object area 78 of the Venue-client object. Moving a functionally-split object such as a Whiteboard object into the shared object area 78 does not entail moving the Whiteboard-server object but just the Whiteboard-client object. The OMF28 instructs the Venue client object to insert the Whiteboard-client object as one of its children. The Whiteboard-client object is then serialised by the Venue-client object and sent to the Venue-server object. The Venue-server object updates its other active Venue-client object with the news that a new Whiteboard object is available in the Venue and these Venue-client objects display the Whiteboard-client object icon in their shared object areas 78 accordingly. The Whiteboard-server object remains on whatever server it was initially stored. Subsequent opening of the Whiteboard object by any of the users of the Venue cause a copy of the Whiteboard-client object to be serialised by the Venue-server and sent to the relevant client-workstation where it is deserialised providing access to the contents of the Whiteboard object for that user. When that user subsequently closes (deactivates) the Whiteboard object, the copy of the Whiteboard-client object remains on that machine for subsequent use.

In contrast, if a NewWave object icon is moved into the shared object area 78 of a Venue-client object, this causes the NewWave object to be serialised and sent from the client workstation to the server machine which stores the relevant Venue-server object. The Venue-server object then instructs its other active Venue-client objects to display the relevant NewWave object icon. Subsequent opening of the NewWave object by a user of such an active Venue-client object causes a copy of the NewWave object to be made and sent to the relevant client workstation. Each such user thus obtains a separate copy of the NewWave object and changes which a user makes are not reflected in the copies held on the other users' machines. This is a consequence of the non-functionally split nature of NewWave objects and is an implementational feature rather than one which is important to the present invention.

There is one Phone Booth server object on every server machine and one Phone Booth client object on every client workstation. The Phone Booth client object arranges for the creation and activation of Venue client objects on client workstations and the Phone Booth server object manages the creation of Venue server objects and the convening of Venues. On opening a Phone Booth client object the user is presented with a directory 90 of possible meeting participants as shown in Figure 11. The directory 90 comprises a list 92 of potential participants, an area 94 for displaying a picture of a participant, a media selection area 96 and an options area 98 displaying three options: Convene, Select and Cancel. Unavailable media options are greyed out in the area 96.

When a name is selected by choosing the Select option and then selecting a name from the directory 90, a picture of that participant appears in the area 94 as shown. The media connections are selectable by checking the relevant boxes in the media selection area 96. Checking the box beside the name of the person in the area 94 adds that person to the list of Venue participants. In addition, the initials of the media options chosen (Phone, Video, Data) appear against the participant's name in the list 92. A previously selected participant can be de-selected by de-checking the box beside the name of that person in the area 94. Taking the Cancel option means that none of the changes made since the window for the directory 90 was brought up will be implemented. The **Convene** option will be described later.

There is also a Connection Manager object on each server machine providing the facility to interconnect users using different media. The Connection Manager object handles the generic operations involved in establishing non-data interconnections. Drivers for each medium available, eg, video, telephone, handle the specific operations involved in carrying out switching requests during use. The Connection Manager object performs the following services:

- maintains a list of media resources available in the system;
- detects when resources fail
- monitors resource channel availability (ie, monitors, microphones, speakers, cameras);
- sets up connections between people using different media;

- point-to-point
- multi-point: all that are available

maintains list of established connections and ensures synchronization with other networks, ie. maintains a model of the state of other networks:

- 5 optimizes switching to prevent unnecessary disconnect -connect transactions;
- provides an interface for monitoring and auditing;
- provides interface to media drivers.

Another functionally split object which is provided in this system is the Whiteboard. A Whiteboard object provides users with a shared computer whiteboard facility so that a user can draw, write and type on his her
10 Whiteboard or acquire an image from another source and the input will be visible to other users viewing the same Whiteboard on different client workstations. Thus the Whiteboard object is an information sharing medium which allows users to look at a picture of what they are discussing.

Figure 12 shows an example of the appearance of a Whiteboard client object. The Whiteboard is being viewed in a window 100 having a title bar 102 and a menu bar 104. A drawing area 106 of the window 100
15 is devoted to displaying the contents of the Whiteboard, in this case a map showing the location of a Hewlett-Packard office. At the bottom of the window 100 is an area 108 indicating the range of tools which are available to the user of the Whiteboard. These tools comprise:

a scroller	110
a pointer	112
a selection of different coloured pens	114
an eraser	116
a text selector	118

20 Apart from the pointer 112, the tools are personal to a user ie each of the users viewing the same Whiteboard could be using the same tool eg. a red pen, without having to wait until another of the users had finished using that tool.

The scroller 110 can be used to scroll the entire window 100 around the Whiteboard. Selecting this tool
30 turns the cursor into a compass enabling the view of the Whiteboard to be click-dragged around by the user.

Only one user can move the pointer 112 at a time. A user takes control of the pointer by clicking on the pointer logo - this turns the cursor into a pointer. At this time, the other users viewing the Whiteboard cannot see the pointer 112. To show the pointer 112, the user needs to click it down at a chosen point in
35 the drawing area 106. The pointer 112 then becomes visible to all of the Whiteboard users at that chosen position. The cursor of the user who has just moved the pointer 112 reverts to the default arrow.

Likewise the seven coloured pens are selectable and deselectable by clicking on the appropriate pen logo, enabling different users to make input in different colours.

The eraser 116 is selectable to remove marks on the Whiteboard. Also, direct typing of text onto the
40 Whiteboard can be done by selecting the text selector 118.

In the area 108 there is also room for a status message 120. As users open or close the Whiteboard other users are notified by a status message.

Modes of operation of a system according to the present invention will now be described, concentrating first on utilization of the Venue.

45 Once a user selects participants and media as described with reference to Figure 11 and selects the Convene option a process of events is initiated to create a new Venue object. Figure 13 shows the objects and the numbered sequence of messages. Figure 13 depicts a server machine S and two client workstations A and B connected to the server machine S. On each client workstation there is initially a Phone Booth client object PB-c. On the server machine S there is initially a Phone Booth server object PB-s and a Connection Manager object CM.

On selecting the **Convene** option using client workstation A, which causes an input (dotted line referenced 1) to the Phone Booth client object PB-c, a message (referenced 2) is sent from the Phone Booth client object PB-c to the Phone Booth server object PB-s on the server machine S causing the Phone Booth server object to create a new Venue server object V-s using a **Venue Start** message (referenced 3).
55 The Phone Booth server object PB-s then sends a **Ring** message (referenced 4) to the Phone Booth client object PB-c on client workstation B causing a dialogue box to appear on the screen of client workstation B inviting the user to take part in the proposed meeting. That user accepts or declines the invitation causing a corresponding message (referenced 5) to be sent from the Phone Booth client object PB-c on client

workstation B to the Phone Booth server object PB-s. If the invitation is accepted a **Create Venue** message (referenced 6) is sent from the Phone Booth server object PB-s to the Phone Booth client object PC-c which causes it to create a new Venue client object V-c on client workstation B involving sending a **Here Is Parent** message (referenced 7) to the new Venue - client object V-c to notify it of the identity of the Venue server object V-s. The new Venue client object V-c then sends a message (referenced 8) to the Venue server object V-s requesting information about the contents of the Venue. The reply from the Venue server object V-s is referenced 9 in Figure 13.

Messages corresponding to those referenced 6-9 are sent between the server S and client workstation A so as also to create a new Venue-client object V-c on that workstation and these messages are referenced 10-13 in Figure 13.

Finally, the Venue server object V-s sends a request (referenced 14) to the Connection Manager object CM to set up the chosen media connections and the Connection Manager object instructs the relevant media drivers accordingly (dotted line referenced 15).

The users of client workstations A and B can then communicate using the newly created Venue.

It is also possible to convene an existing Venue by selecting the **Convene** option within the Venue. This initiates a sequence of events which will be described with reference to Figure 14. Again, a server machine S and two client workstations A and B are represented.

The user selection of the **Convene** option is referenced 1 in Figure 14. This causes the Venue client object V-c to send a **Convene Request** message (referenced 2) to the Venue server object V-s which notifies the Phone Booth server object PB-s of the convene request in a message referenced 3 which identifies the intended meeting participants. The Phone Booth server object PB-s sends a **Ring** message (referenced 4) to the Phone Booth client objects PB-c on the workstations of the intended meeting participants causing a dialogue box to be displayed on these workstations inviting the users to partake in a meeting. When these users accept or decline the invitation this causes a reply message (referenced 5) to be sent from each Phone booth client object PB-c to the Phone Booth server object PB-s.

The next step is for the Phone Booth server object PB-s to instruct (message referenced 6) the Phone Booth client objects PB-c to create new Venue client objects V-c on machines where a Venue client object linked to the Venue server object V-s is not already stored. Such new Venue client objects V-c then send a message (referenced 8) to the Venue server object V-s requesting information about the contents of the Venue so that the appropriate icons can be displayed in the shared area 78 of Figure 10 on the respective client workstations. The reply message containing information about the contents of the Venue from the Venue server object V-s is referenced 9 in Figure 13.

The Venue server object V-s then sends a request (referenced 10) to the Connection Manager object CM to set up the chosen media connections and the Connection Manager object instructs the relevant media drivers (not shown) accordingly (dotted line referenced 11). The distributed meeting can then proceed.

A user can also set up a new Venue by selecting a **Create a New** menu option in NewWave Office (Figures 14-17 of Appendix A). On opening the new Venue-client object a Venue-server object also needs to be created. Figure 15 depicts the process. A server machine is indicated by S and a client workstation by C.

The act of opening the new Venue-client object V-c causes it to send a message (referenced 1) to the Phone Booth client object PB-c which triggers a message (referenced 2) to be sent from the Phone Booth client object PB-c to the Phone Booth server object PB-s requesting creation of a new Venue server object V-s. The Phone Booth server object PB-s creates a new Venue server object V-s using a **Venue Start** message (referenced 3). Next the new Venue-server object V-s sends a **Here Is Parent** message (referenced 4) to the Venue-client object V-c containing the ID of the Venue-server object. The new Venue client object V-c then sends a message (referenced 5) to the Venue server object V-s requesting information about the contents of the Venue and there is a corresponding reply (referenced 6) from the Venue server object.

It is possible to add new meeting participants to an active Venue by selecting an **Add New Member** menu option. This causes a directory of potential participants to be displayed as shown in Figure 11 to enable the selection of one or more further participants and associated media connections. Information on these choices is conveyed from the Venue client object to the Venue server object which updates the control panels of the relevant Venue client objects. Chosen new meeting participants are not aware of any change until someone convenes a meeting.

When a user elects to close a Venue by selecting a **CLOSE** option this causes a message to be sent from the relevant Venue-client object to its Venue-server object informing the Venue-server object that the Venue-client object is deactivating. The Venue-server object then messages the Connection Manager object

to disconnect the media connections for the Venue-client object which is deactivating. The Venue-server object sends messages to all of its other Venue-client objects informing them of the deactivation of the particular Venue-client object so that these other Venue-client objects alter their appearance to indicate that the relevant meeting member is now absent.

5 Another way of setting up a distributed meeting is for a user to copy an existing Venue-client object to the desired meeting participants. A Venue-client object is a reference to a Venue-server object. Copying a Venue-client object to other workstations creates a reference to the relevant Venue-server object on those other workstations because in the copying process the Venue-client object's reference to its Venue-server object is preserved.

10 There are different ways in which a Venue-client object can be copied to other workstations. One way is to include the Venue-client object in an electronic mail message. For this option, an electronic mail message is created in the normal manner e.g. using Hewlett-Packard's NewWave Mail and a Venue-client object is included in the message using a standard copy operation. When the or each addressee receives the message, they place the Venue-client in their collection of objects in preparation for the forthcoming meeting. At the relevant time, the meeting participants open their Venue-client objects to commence the meeting. On opening the Venue-client objects, their 32 bit machine IP address is automatically updated and the Venue-client objects send a Here Am I message to the associated Venue-server object.

Another option is for the user wishing to set up a distributed meeting to copy the relevant Venue-client object and to serialise the copy of the Venue-client object to a file on floppy disc (or other shared medium such as a network drive). This file may then be transported to the workstations of the intended meeting participants and deserialised thereby providing each of these participants with a copy of the Venue-client object and thereby means for accessing the associated Venue-server objects in order to take part in the distributed meeting.

A new Whiteboard-client object can also be created using the "Create A New" option in NewWave Office. On opening the Whiteboard-client object a new Whiteboard server object needs to be created. The process is analogous to that described with reference to Figure 15 replacing references to Venue objects with references to Whiteboard objects.

A new Whiteboard object can also be created inside a Venue by selecting the "Create a New" option inside the Venue. In this case, the Venue-client object automatically activates the new Whiteboard-client object in order to initiate creation of a new Whiteboard server object (again using a process analogous to that shown in Figure 15).

In the same manner as a Venue-client object can be copied and transmitted in an electronic mail message or via floppy disc, a Whiteboard-client object can be so utilised. Again the advantage of creating a reference to the relevant Whiteboard server object for the recipients of the copied Whiteboard-client objects is obtained since each copy of the Whiteboard-client object contains a reference to the Whiteboard server object (as described with reference to Figure 8).

Also as previously described, a Whiteboard-client object can be moved into the shared items area of a Venue object by a user causing copies of the Whiteboard-client object to be made available to the other users of the Venue object thereby giving access to the associated Whiteboard server object to these users.

40 An exemplary user session will now be described with reference to Figures 16 to 33 involving hypothetical users Martin, Richi and Ed.

Figure 16 shows a screen of a client workstation (Martin's) running Hewlett Packard NewWave Software. A window 126 has:

- a title bar 128 carrying the title "NewWave Office";
- 45 a menu bar 130 offering the following options:
Action, Edit, Objects, View, Settings, Task and Help;
- a system menu box 132;
- size boxes 134 and 136;
- a vertical scroll bar 138 with scroll arrows 140 and 142 and a scroll box 144;
- 50 a horizontal scroll bar 146 with scroll arrows 148 and 150 and a scroll box 152;

The window 126 displays icons for some standard tools at the top: Waste Basket 154, Agent 156, Printer 160, In Tray 162, Out Tray 164, File Drawer 166. The icons 168, 170 and 172 respectively on the left hand side represent work-related items:

- 55 "Project Meeting" a Venue-client object representing a reference to a Venue server object on the local server machine;
- "Design Notes" a Whiteboard-client object representing a reference to a Whiteboard server object on the local server machine;
- "Design Principles" a NewWave document object fully contained on the client workstation.

To "open" an object, the user double clicks on the relevant icon. Referring to Figure 17, Martin has opened the Project Meeting Venue which is shown in a window 174. The window 174 has a menu bar 176 which has similar options to the menu bar 130 of the window 126 except a Meeting option instead of the Setting option. The window 174 displays a participants area 178, showing only Martin, and a shared items area 180 which is empty. Underneath a bit map 182 of Martin is a name bar 184 which includes a notification of presence and three media control buttons 185-7 for Phone, Video and Data respectively. Only the Data button 187 is highlighted in this example, ie. blacked out in Figure 17.

On selecting the Meeting option from the menu bar 176 of the window 174, a CoMedian directory window 190 appears, Figure 18. The reference numerals for the CoMedian directory which were used in Figure 11 will be retained here. Martin selects the name Richard Jennings from the list 92 of potential participants causing a picture of Richard to appear in the area 94 together with crosses in the video and data boxes in the area 96 to indicate Richard's media selections. This means that Richard will be contacted through the system for data sharing with both video and audio travelling over video connections. Martin then clicks on the Convene button in the options area 98 to add Richard to the Venue which causes Richard's image to join Martin's image in the Venue as shown at 192 in Figure 19. Richard is marked as absent at 194 and a banner 196 is displayed indicating that he has been invited. Martin has selected both video and data connections for himself in order to match what was selected for Richard. This causes the video and data buttons 186 and 187 to be highlighted in a first colour to show that they are currently in use albeit only locally to Martin's own workstation. Richard's video and data media buttons 186a and 187a are highlighted in a second colour to indicate that they have been requested but are not yet in use.

While waiting for Richard to join the Venue, Martin is moving the Design Notes and Design Principles objects 170 and 172 into the shared items area 180 of the Venue by clicking on each object and dragging it to the area 180.

Moving now to Richard's workstation, shown in Figure 20, the invitation to join the Venue has reached his machine and has caused a bell 200 to appear at the bottom of his screen. The bell 200 is flashing and making a ringing sound to attract his attention. Richard clicks on the bell 200 and the result is shown in Figure 21. An invitation message box 202 is brought up telling Richard that he has been invited to a meeting and giving the name of the meeting and the name of the person who convened the meeting. The invitation message box 202 comprises two options: Accept and Decline. Richard clicks on the Accept option to accept the invitation to join the meeting.

Referring to Figure 22 accepting the invitation causes a Venue client object automatically to be created and a window 204 to be opened for Richard. The chosen media connections have been set up so that Richard can now see and hear Martin and the objects that Martin has placed into the shared items area 180 are available to him. Figure 23 shows that Martin can see the same Venue having the same contents on his workstation. Referring to Figure 24, during the meeting, Martin has opened a window 206 on the Design Notes whiteboard object. Martin informs Richard of this so that Richard can also view the whiteboard object and then both Martin and Richard can scribble on the whiteboard and view each others input. When their meeting is finished both Martin and Richard close and save the Venue.

Figure 25 shows the Venue object 168 saved in Richard's NewWave office. In Figure 26, Richard has just opened his NewWave office and is viewing the Venue 168 in a window 208. Martin is not present (although he would be if, coincidentally, he had his Venue open at the same time as Richard. In that situation, the relevant media connections would automatically be set up). Referring to Figure 27, Richard has selected the Meeting menu item using the cursor 210 so as to bring up the CoMedian directory 212 and he has selected Ed Davies in the manner previously described. Ed Davies does not have video capability, instead he is selected by telephone. Clicking on the Select button will cause Ed to be added to the Venue without beginning a Convene operation.

Referring to Figure 28, Richard is about to initiate a Convene operation by selecting the Action item from the menu bar 214 of the window 208, and selecting the Convene option from the corresponding menu 216. Since Ed does not have video capabilities, the audio from his telephone would be mixed into the video feed into Martin and Richard and their audio signals would be sent to Ed's telephone during their distributed meeting.

Turning now to Figure 29, a new session is beginning on Richard Jennings's workstation. A window 220 contains Richard's NewWave Office. Richard has created an outgoing message represented by the icon 222 called "Meeting Request" (using the "Create a New" option from the Action Menu - see Figures 14 to 17 of Appendix A). In Figure 30, on opening the outgoing message 222 it is displayed in a window 224. Richard has completed the distribution list 226 and written a cover note 228.

Referring to Figure 31, a new Venue-client object represented by the icon 230 is created (again using the "Create a New" option). The Venue-client object 230 is copied and dragged into the window 224

displaying the message. This is achieved by clicking on the icon 230 and pressing the control key whilst dragging the icon into the message. (This is an alternative method from the user perspective to the copy procedure described with reference to Figures 18-20 of Appendix A.) The bar 232 labelled "Part 3" in Figure 32 shows that the message now contains a copy of the Venue-client object. The message window 5 224 is then closed (Figure 33). To send the message 222 it can be dragged onto the Out Tray icon 234. This causes a copy of the message, including the Venue-client object which it contains, to be sent to the people on the distribution list. The Out Tray object 234 initiates the serialisation of the message components to enable these to be transmitted over the network. On receipt at the respective destinations, the In Tray object represented by icon 236 deserialises the message components so that these can be 10 viewed and manipulated by the recipients. The recipients can drag the Venue-client object out of the message and into their main NewWave Office window (220). At the appointed time, the three participants open their Venue-client objects to begin a distributed meeting. During the meeting, the users can open shared objects e.g. a Whiteboard object, and modify these interactively as well as interacting through their telephone and video interconnections. For example, input made by each user to a Whiteboard-client object 15 is relayed to the Whiteboard server-object which updates all of the other corresponding active Whiteboard-client objects of the changes.

Although only Venue shared objects and Whiteboard shared objects are available to a user in this embodiment, it is envisaged that further possibilities for shared objects are a fax object, a discourse structurer object and tools to control the external media such as a virtual monitor manager and a video 20 cassette recorder controller.

It is envisaged that a system according to the present invention may not entail the use of dedicated server machines but that server objects could run on user workstations given a suitable inter-object messaging infrastructure.

Brief Description of the Drawings

25

Figure 1 is a block diagram of a computer in accordance with the preferred embodiment of the present invention.

30

Figures 2 and 2A show block diagrams which illustrate the relationship between objects, applications and data files in accordance with the preferred embodiment of the present invention.

35

Figure 3 shows a plurality of objects linked in accordance with a preferred embodiment of the present invention.

40

45

50

55

Figure 4 shows a series of objects serving as folders, as parents of objects containing data, in accordance with a preferred embodiment of the present invention.

Figure 5 illustrates the screen display which results from linking of various objects in accordance with a preferred embodiment of the present invention.

Figure 6 shows the linking of objects in order to create the screen display shown in Figure 5.

Figure 7 shows how three objects may be linked together in accordance with a preferred embodiment of the present invention.

Figure 8 and Figure 9 illustrate how an object may be copied in accordance with a preferred embodiment of the present invention.

Figure 10 and Figure 11 illustrate the copying of a public object in accordance to a preferred embodiment of the present invention.

Figures 12 through Figure 71 show the appearance on a screen of a session in which a user manipulates objects in accordance with a preferred embodiment of the present invention. Also shown are block diagrams of how objects appearing to the user are linked in accordance to the preferred embodiment of the present invention.

Figure 72 is a block diagram of an Object Management Facility (OMF) in accordance with the preferred embodiment of the present invention.

Figure 73 shows a block diagram of the organization of HPOMF.CAT, a system file included in the OMF shown in Figure 72.

Figure 74 shows the relation between a global parent and global objects in accordance with the preferred embodiment of the present invention.

Figure 75 is a block diagram which shows how system files within the OMF shown in Figure 72 accesses data files and applications from a memory shown in Figure 1.

Figure 76 is a block diagram of the organization of the memory shown in Figure 75.

Figure 77 and Figure 78 show objects and links in accordance with the preferred embodiment of the present invention.

Figure 79 is a block diagram of the organization of HPOMF.XRF, a system file included in the OMF shown in Figure 72.

Figure 80 shows a view specification record in accordance with the preferred embodiment of the present invention.

Figure 81 shows the use of a snapshot in accordance with a preferred embodiment of the present invention.

Figure 82 shows the data path of a view when there is no snapshot, in accordance with a preferred embodiment of the present invention.

5 Figure 83 shows the data path of a view when there is a
snapshot, in accordance with a preferred embodiment of the
present invention.

10 Description of the Preferred Embodiment

15 Figure 1 shows a computer 18 having a monitor 14, a
keyboard 19 and a mouse 20. A portion of computer main
memory 17 is shown by an arrow 9 to be within computer 18.
20 Within computer memory main 17 is shown an object management
facility (OMF) 100, an application 101, an application 102,
an application 103, an application 104, an application 105
25 and an application 106.

Each of applications 101 to 106 store data using
30 objects. For instance, in Figure 2, application 101 is
shown to have stored data using an object 202, an object
203, an object 204 and an object 205. Similarly,
35 application 106 is shown to have stored data in an object
207, an object 208, an object 209 and an object 210. OMF
40 100 stores information indicating which objects go with
which application. Objects which are associated with a
single application are considered to be objects of the same
45 type, or the same class. For instance, object 202, 203, 204
and 205 are of the same class because each is associated
with application 101. Similarly objects 207, 208, 209 and
50 210 are of the same class because each is associated with
application 106. All objects of the same class use the same
55 application. When an application is being run by computer

18, OMF 100 informs the application which object the
 5 application should access for data. That object is then
 considered to be active. An object is inactive when the
 application the object is associated with is not being run
 10 by computer 18, or when the application the object is
 associated with is being run, but is not being run with the
 15 data of that object.

Active objects can communicate with each other using
 messages. For example if two instances of application 101
 20 are being run by computer 18, one with the data of object
 202 and the other with the data of object 203, object 202
 25 and object 203 are both active. Therefore object 202 may
 send a message 211 to object 203. Similarly, if computer 18
 is running application 101 with the data of object 202, and
 30 is running application 106 with the data of object 207,
 object 202 and object 207 are both active. Therefore,
 35 object 202 may send a message 212 to object 207.

Messages, such as message 211 and 212 may be formatted
 to be sent and received by all types of objects. This
 40 allows for free communication between all active objects.
 This also allows new object types to be defined and added to
 45 the system without requiring that the existing object types
 be updated to use the new type.

Each object has associated with ^{it} a set of data files.
 50 For instance, object 210 is shown to have associated with it
 a data file 221, a data file 222 and a data file 223. Data
 55

5 in data files 221, 222 and 223 are in a format which can be
interpreted by application 106.

10 Each object has associated with it a list of
properties. Each property has a name and a value which may
be accessed by specifying the name. In addition, each class
of objects has associated with it a list of properties that
15 are common to all objects of that class. For instance, in
Figure 2A, object 205 and application 101 are shown. Object
20 205 has associated with it a property 231, a property 232,
and a property 233. Application 101 has associated with it
a property 131, a property 132 and a property 133.

25 Property lists can contain any number of properties.
Each property value can be from zero to 3,2762 bytes in
length. Properties are used to store descriptive
30 information about objects and classes, such as names,
comments and so on.

35 Objects may have references to other objects. These
references are called links. Links are directional: one
object is called the parent, the other the child. Each link
40 has a reference name which is a number that is assigned by
the parent object to identify each of its children. All of
45 an object's children, its children's children, and so on are
collectively called that object's descendents. Similarly,
an object's parents, its parents' parents, and so on, are
50 collectively called that object's ancestors. In the
preferred embodiment of the present invention, an object
55 which may be manipulated by a user, can have zero or more

children and one or more parents. An object is not
5 allowed to become its own descendent.

In Figure 3 is shown an object 301, an object 302, an
10 object 303, an object 304, an object 305, an object 306, an
object 307, an object 308 and an object 309. Objects 301-
309 have links with reference names which are numbers shown
15 in parenthesis by each link. Object 301 has a link 310,
with reference name "1", to object 302. Object 301 has a
20 link 311, with reference name "2", to object 303. Object
302 has a link 312, with reference name "7", to object 304.
Object 302 has a link 313, with reference name "8", to
25 object 305. Object 303 has a link 314, with reference name
"1", to object 306. Object 303 has a link 315, with
30 reference name "4", to object 307. Object 304 has a link
316, with reference name "1", to object 308. Object 305 has
a link 317, with reference name "7", to object 308. Object
35 306 has a link 318, with reference name "8", to object 309.
Object 307 has a link 319, with reference name "9", to
object 306. Object 307 has a link 320, with reference name
40 "13", to object 309. Object 308 has a link 321, with
reference name "1", to object 309. Object 308 has a link
45 322, with reference name "3", to object 303.

Object 301 is a parent of 302 and 303. Object 303 is a
50 child of object 301 and of object 308. Each of objects 302-
309 are descendents of object 301. Descendents of object
303 are objects 306, 307 and 309. Object 309 has for
55

ancestors all of objects 301-308. Object 303 has for
5 ancestors objects 301, 302, 304, 305 and 308. And so on.

Active objects can dynamically make and delete links to
10 other objects. When a link to an object is deleted, OMF 100
checks if the object has any other parents. If not, OMF 100
destroys the object by deleting the data files of the object
15 and reclaiming other storage space associated with the
object.

Object links may be used for various purposes. For
20 example, folders may be in the form of objects. The
children of objects used as folders may be objects
25 containing data for use with various applications, or the
objects may be other folders. Figure 4 shows an example
of the use of objects as folders. An object 401 (also
30 called folder 401), an object 402 (also called folder 402),
an object 403 (also called folder 403) and an object 404
35 (also called folder 404) are used as folders. Folder 401
contains an object 405, used to contain data, an object 406,
used to contain data, an object 407, used to contain data,
40 and folder 402. Folder 402 contains an object 408, used to
contain data, folder 403 and folder 404. Folder 403
45 contains an object 409, used to contain data, and an object
410, used to contain data. Folder 404 contains an object
50 411, used to contain data, an object 412, used to contain
data and an object 413, used to contain data.

A more sophisticated use of links is to construct
55 compound objects. For instance in Figure 5, a document 510

5 contains lines of text 511, lines of text 512, a graphics
figure 513, a graphics figure 514 and spreadsheet data 515.
As shown in Figure 6, text and formatting data is stored in
10 an object 611, graphics data for graphics figure 513 is
stored in an object 612, graphics data for graphics figure
15 514 is stored in an object 613 and spreadsheet data 515 is
stored in object 614. Links that are used to build compound
objects always have some kind of data transfer associated
20 with the link and hence are called data links. In Figure 6
is shown a data link 615, a data link 616 and a data link
25 617. In document 510, data from object 612, object 613 and
object 614 are merely displayed, therefore data link 614,
data link 615 and data link 616 are visual data links. In a
30 visual data link, the parent will send requests to its child
to display data within the parent's window.

35 In Figure 7, an object 701, which contains data for a
first spreadsheet, is linked through data link 704 to an
object 702, which contains data for a second spreadsheet,
40 and is linked through data link 705 to an object 703, which
contains data for a third spreadsheet. The first
spreadsheet uses data from the second spreadsheet and from
45 the third spreadsheet. Since the first spreadsheet does
more than merely display data from the second and the third
50 spreadsheets, data link 704 and data link 705 are called
data-passing data links.

55 OMF 100 does the "bookkeeping" when objects are copied
or mailed. When an object is copied, OMF 100 makes copies

of data files associated with the object. If the object
5 being copied has children, OMF 100 also makes copies of the
object's descendants, and builds links between the new
10 objects to give the new compound object the same structure
as the original.

For instance, Figure 8 shows object 308, from Figure 3,
15 and the descendants of object 308. When OMF makes a copy of
object 308, OMF copies each of object 308's descendants and
the links shown in Figure 8. Figure 9 shows a copy of
20 object 308. Object 308a is a copy of object 308. Object
303a is a copy of object 303. Object 306a is a copy of
25 object 306. Object 307a is a copy of object 307. Object
309a is a copy of object 309. Link 321a is a copy of link
321. Link 322a is a copy of link 322. Link 314a is a copy
30 of link 314. Link 315a is a copy of link 315. Link 318a is
a copy of link 318. Link 319a is a copy of link 319. Link
35 320a is a copy of link 320.

In the preferred embodiment, the default behavior
40 results in the copy of a parent's children when the parent
is copied. However, when a child is designated as "public"
it is not copied. Rather, a copy of the parent includes a
45 link to the child. For instance, in Figure 10, a parent
object 161 is to be copied. Parent object 161 is linked to
a child object 162 through a link 163. Child object 162 is
50 a public object. As shown in Figure 11, copying of parent
object 161 results in new object 161a being linked to object

162 through a new link 163a. Object 161a is a copy of
5 object 161. Link 163a is a copy of link 163.

In Figure 12 through Figure 71, it is shown how objects
10 are displayed to a user on monitor 14. In Figure 12 a
"NewWave Office" desktop is shown to include icons labelled
as "File Drawer", "Waste Basket", "Diagnostic", "Printers",
15 "Star" and "My Folder". A user (not shown) has manipulated
a cursor 781, using keyboard 19 or mouse 20, to select "My
20 Folder".

Figure 13 shows how the objects displayed on monitor 14
are linked. NewWave Office (shown as an object 700) is the
25 parent of "File Drawer" (shown as an object 701) through a
link 711, of "Waste Basket" (shown as an object 702) through
a link 712, of "Diagnostic" (shown as an object 703) through
30 a link 713, of "Printers" (shown as an object 704) through a
link 714, of "My Folder" (shown as an object 705) through a
link 715 and of "Star" (shown as an object 706) through a
35 link 716.

In Figure 14, the user, using cursor 781, has selected
40 "Create a New..." in a pull down menu 782. As a result of
this selection a dialog box 779 appears as shown in Figure
15. Using cursor 781, the user has highlighted the icon
45 "Layout" and using keyboard 19 has typed in the name "Paste
Up" as a name for a new object to be created. Cursor 781
50 now points to a region labelled "OK". Once this region is
selected, a new object titled "Paste Up" is created, as is
55 shown in Figure 16.

In Figure 17, "Paste Up" is shown as an object 707
5 linked as a child of NewWave Office through a link 717.

The basic clipboard operations are Cut, Copy, and
10 Paste. The user must select the data that is to be moved or
copied, and then give either the Cut command or the Copy
command. Cut moves the selected data to the clipboard
15 (deleting it from its original location). Copy makes a copy
of the selected data on the clipboard. The user must then
select the location where he wants the data to be moved or
20 copied to, and give the Paste command. This command copies
the contents of the clipboard to the selected location.

In Figure 18 a user is shown to have selected "Paste
25 Up". The selection is represented by the icon for "Paste
Up" being displayed using inverse video. With cursor 781,
30 the user selects "Copy" from a pull down menu 783. In
Figure 18A a Clipboard object 720 is shown to be a parent of
35 an object 708 through a link 721. Object 708, is a copy of
object 707 ("Paste Up").

As shown in Figure 19, next the user selects "Paste"
40 from pull down menu ^u783. The result, shown in Figure 20, is
the addition of an object 708, pointed to by cursor 781,
45 which is a copy of the original "Paste Up" object 707.

In Figure 21, the new object is shown as object 708
linked as a child of NewWave Office through a link 718.

50 In Figure 22, "My Folder", has been opened by double
clicking the icon for "My Folder" using cursor 781. The
result is a new window 785 representing "My Folder".
55

In Figure 23, using cursor 781, "Paste Up" (object 708) is shown being dragged to window 785. In Figure 24, the process is complete and "Paste Up" (object 708) is now in window "My Folder". In Figure 25, "Paste Up", shown as object 708, is now a child of "My Folder" through link 728.

The user sets up multiple links by using the Share command. This command is an extension of the clipboard metaphor common in software packages today for moving and copying data around the system. The clipboard is a special buffer that the system uses to hold data that is in transit.

In one way, the Share command operates similarly to the Cut or Copy command described above. That is, using Share, Cut, or Copy, the user selects some data first and then gives the Share command, which results in something being put on the clipboard. In the case of the Share command, however, what is put on the clipboard is neither the actual data nor a copy of the actual data. Instead, it is a link to the selected data. When this link is pasted, a permanent connection is made between the original data and the location of the Paste. Through use of OMF 100, this link is used by the involved applications to provide easy access to the original data (in its full application) and automatic updating when the original data is modified.

In Figure 26, the NewWave Office window has been activated. "Paste Up" (object 707) has been selected, as evidenced by "Paste Up" (object 707) being in inverse video. Using cursor 781, "Share" from menu 783 is selected. In

Figure ^{26A}~~720~~, Clipboard object 720 is shown to be a parent of
5 "Paste Up" object 707 through a link 722.

10 In Figure 27, window 785 has been activated. From a
menu 787, "Paste" is selected. The result, shown in Figure
28, is an icon 707a appearing in window 785, which indicates
that "Paste Up" (object 707) is shared by window 785 and the
15 NewWave Office window. In Figure 28A, as a result of the
paste, "Paste Up" is now shown to be both a child of
Clipboard 720 through link 722 and a child of "My Folder"
20 705 through a link 727. In Figure 29, showing just the
interconnection of objects visible to the user, "Paste Up"
25 (object 707) is shown to be a child of "My Folder" 705
through link 727. Since "Paste Up" (object 707) is shared,
not copied, "Paste Up" (object 707) remains a child of
30 NewWave Office through link 717.

One key feature of data links is automated data
35 transfer. When a child object is open and the user changes
a part of it which is "shared out", then it makes a call to
OMF 100. OMF 100 checks if any of the object's parents
40 "care" about this particular change. If they care and if
they are also open, OMF 100 sends to the parents a message
45 informing them that new data is available. The parent can
then send messages to the child to produce or display the
data. This feature allows the user to establish compound
50 objects with complex data dependencies, and then have
changes made to any sub-part be automatically reflected in
55 other parts. For example, changing a number in a

spreadsheet could cause a graph to be re-drawn, and updated
5 as a figure in a document. And since an object can have
many parents, a single object can be used as "boiler plate"
10 for any number of other objects. A change in the boiler
plate will be reflected in all the objects which have links
to it. Automated data transfer is illustrated in the
15 following discussion.

In Figure 30, window 785 for "My Folder" has been
20 closed. In Figure 31, cursor 781 is used to select "Create
a New..." from pull down menu 782. As a result of this
selection dialog box 779 appears as shown in Figure 32.
25 Using cursor 781, the icon HPText has been highlighted and
using keyboard 19 the name "Sample Text" has been typed in
as the name for a new object to be created. Cursor 781 now
30 points to a region labelled "OK". Once this region is
selected, a new object titled "Sample Text" is created, as
35 is shown in Figure 33.

In Figure 34, "Sample Text" (object 709) is shown to be
40 a child of NewWave Office through a link 719. In Figure 34,
since "My Folder" has been closed, "Paste Up" (object 708),
link 728 and link 727 are not shown. However, these still
45 exist, but are not currently visible to a user.

In Figure 35, placing cursor 781 on the icon "Sample
50 Text" and double clicking a button on mouse 20 results in
"Sample Text" being opened. In Figure 36, an open window
789 for "Sample Text" is shown.

In Figure 37 a window 791 for "Paste Up" (object 707) has been opened by double clicking on the icon for "Paste Up". In Figure 38, using Cursor 781, controlled by mouse 20, a portion 790 of the text of "Sample Text" has been selected. The portion in inverse video stating "New Wave Office environment" is portion 790.

In Figure 39, cursor 781 is used to select the selection "Share" in a pull down menu 792. In Figure 40, an area 793 in window 791 is selected using cursor 781. In Figure 41, a selection "Paste" is selected from a pull down menu 794 using cursor 781. In Figure 42, "Sample Text" is linked to "Paste Up" (object 707) and displayed text 790 is displayed in "Paste Up" window 791. In Figure 43 "Sample Text" (object 709) is shown to be a child of "Paste Up" (object 707) through a link 729. In Figure 42, displayed text 790 is shown in gray because "Star" window 789 is open. In Figure 44, "Star" window 789 is closed so displayed text 790 is clearly displayed.

In Figure 45, a region 795 of window 791 is selected using cursor 781. Figure 46 shows cursor 781 dragging the icon "Star" into region 795 of window 791.

In Figure 47, data from "Star" (object 706) is now displayed in region 795 of window 791. As may be seen in Figure 48, "Star" (object 706) is now a child of "Paste Up" (object 707) through a link 726.

In Figure 49, a user has placed cursor 781 over region 795 of window 791 and double clicked a button on mouse 20.

The result is the opening and display of "Star" (object 706) in a window 796. Figure ⁵⁰~~40~~ shows the use of cursor 781 to select selection "Ellipse" in a menu window 797 which results in the data within "Star" (object 706) being changed from a star to an ellipse. As shown in Figure 51, the result is a change both in data displayed in window 796 and data displayed in region 795 of window 791.

In Figure 52, cursor 781 is used to define a region 797 in window 791. In Figure 53, cursor 781 is used to select a selection "Create a New..." in pull down menu 798. As a result of this selection dialog box 799 appears in Figure 54. Dialog box 799 contains icons for the two classes of objects available which are able to display data in region 797 of window 791. Using cursor 781, the icon "HP Shape" has been highlighted. Using keyboard 19 the name "New Shape" has been typed in as the name for a new object to be created. Cursor 781 now points to a regions labelled "OK". Once this region is selected, a new object titled "New Shape" is created. Data for "New Shape" is displayed in region 797 of window 791 as is shown in Figure 55. In Figure 56, "New Shape", (object 750) is shown to be a child of "Paste Up" (object 707) through a link 760.

In Figure 57 a window 800 for "New Shape" was opened by placing cursor 781 over region 797 of window 791 and clicking twice on a button on mouse 20. In Figure 58, cursor 781 is used to select the selection "Triangle" from a pull down menu 801. The result, as shown in Figure 59, is

5 that a triangle is now displayed both in window 800 and in
region 797 of window 791.

10 In Figure 60, window 800 has been closed. In Figure
61, "New Shape" is selected by placing cursor 781 over
region 797 of window 796, and clicking a button on mouse 20.
In Figure 62, cursor 781 is used to select selection "Share"
15 from pull down menu 794. In Figure 63, cursor 781 is used
to select a region 802 of window 791. In Figure 64, cursor
781 is used to select selection "Paste" from pull down menu
20 794. The result, as shown in Figure 65, is the sharing of
"New Shape" with data from "New Shape" being displayed in
region 797 and in region 802 of window 791. In Figure 66,
"New Shape" (object 750) is shown to have an additional link
25 770, from its parent "Paste Up" (object 707).

30 In Figure 67, region 797 has been selected using cursor
781. Cursor 781 is then used to select selection "Cut" from
pull down menu 794. The result, as seen in Figure 68, is
35 that region 781 has been removed from window 791. In Figure
69, cursor 781 is used to select selection "Paste" from pull
down menu 783. The result, shown in Figure 70, is an icon
40 for "New Shape", pointed to by cursor 781. In Figure 71,
"New Shape" (object 750) is shown to now be a child of
45 NewWave Office (object 100), through a link 780.

In Figure 72, OMF 100 is shown to contain seven system
50 files: system file 601, system file 602, system file 603,
system file 604, system file 605, system file 606 and system
file 607. OMF interface 599 serves as interface of OMF to
55

other programs running on computer 18. System files 601-607 serve as a data base that provides various information.

5 They provide information about object properties such as what class each object is what is the name of each object. System files 601-607 provide information about classes of
10 objects such as what application is associated with each class of objects, what icon represents objects of a particular class and lists of what messages (such as those
15 shown in Figure 2) can be processed by objects of a particular class. System files 601-607 also contain information about links between parent and child objects
20 including a list of parents and reference names of each link from a parent for each object; a list of children and reference names of each link to a child for each object; and
25 additional information to manage data exchange across data links. Additionally, system files 601-607 contain general information such as what files are installed in the
30 operating system for each class that is installed, and what objects have requested automatic restart when the OMF 100 is restarted.

40 In the preferred embodiment of the present invention system file 601 is referred to as HPOMF.CAT, system file 602 is referred to as HPOMF.CLS, system file 603 is referred to
45 as HPOMF.XRF, system file 604 is referred to as HPOMF.PRP, system file 605 is referred to as HPOMF.INS, system file 606 is referred to as HPOMF.SDF and system file 607 is referred
50

to as HPOMFICO.NWE.. A description of each system file is now given.

5 System file 601, HPOMF.CAT, is also referred to as
SYSCAT. HPOMF.CAT is a catalog of all the existing objects
10 in the system. In Figure 73, HPOMF.CAT is shown to be
record oriented. HPOMF.CAT has a plurality of file records.
In Figure 73, file record 0 through file record 8 are shown,
15 although HPOMF.CAT may contain many more file records than
are shown in Figure 73. File record 0 is a header which
contains various signatures and is used to manage a list of
20 free file records. A signature is some known value which if
present indicates that the file is not corrupted. File
25 record 1 through file record 8 and additional file records
(not shown) either define an existing object, or are free.
In the preferred embodiment HPOMF.CAT can grow dynamically,
30 as more file records are needed, but cannot shrink.

File record 1 defines a special object called the
35 global parent. The global parent has a form different than
every other object, and may be regarded as a "pseudo"
object. Figure 74 shows the global parent to be the parent
40 of global object 250 through link 260, global object 251
through link 261, global object 252 through link 262, global
45 object 253 through link 263, global object 254 through link
264 and global object 255 through link 265, as shown.
Global objects 250-255 are also within HPOMF.CAT. Each
50 global object 250-255 may be a parent of one or more objects
in HPOMF.CAT. Each object in HPOMF.CAT which is not a

55

global object, is a descendent of global object. Although
 Figure 74 shows only six global objects, the number of
 global objects operating on a system is a matter of system
 configuration. Any object in the system can refer to a
 global object by ~~by~~ using the reference name of the link to
 that global object from the global parent.

As may be seen from Figure 73, file records in
 HPOMF.CAT are numbered consecutively. These numbers serve
 as tags, which identify each object.

In the preferred embodiment of the present invention,
 each record is 128 bytes in length. The fields for file
 record 0 are listed in Table 1 below:

Table 1

1FirstFreeEntry	Contains the record number of the first free record in HPOMF.CAT, or "0" if there are no free records.
FileId	Contains the null terminated string "HPOMF.CAT". This serves as a signature.
Version	Contains the file format version number, which also serves as a signature.
1MaxRecordNumber	Contains the number of the highest record ever allocated from within HPOMF.CAT (this highest record may or may not be free).

Table 2, below, contains the fields for file records in
 HPOMF.CAT for file records other than file record 0:

Table 2

5	lFirstFreeEntry	Is "-1" if this record defines an object, otherwise this record is free and this field is the record number of the next free record, or "0" if there are no more free records. If the record is free, none of the other fields in the record is meaningful.
10		
15	TypeInClass	Specifies the class of this object. This is the number of the record in HPOMF.CLS that indicates to which class the object belongs (see discussion of class above).
20		
	SysCatFlags	Specifies if the object is global if the bit masked by the number 20 (hexadecimal) is set in this byte. In the preferred embodiment all other bit positions must contain "0" and are not used.
25		
30	properties	Specifies the number of properties, the length of the property names and the location in HPOMF.PRP of the object's properties. See the description of HPOMF.PRP below for further definition of the structure of this field.
35		
40	fastprops	Certain object properties, such as name, are so heavily accessed that they are stored directly in this field, rather than indirectly in the properties file. Properties stored in this field are called "fast properties."
45		

50 System file 602, HPOMF.CLS is also referred to as
 SYSCLASS. This system file is a list of all installed
 classes in the system. It is record oriented. The first
 55 record, numbered 0, is a header which contains various

signatures (see above) and is used to manage a list of free
 5 records. All other records either define an installed class
 or are free. In the preferred embodiment HPOMF.CLS can grow
 dynamically, but cannot shrink.

10 Each file record in HPOMF.CLS is thirty-two bytes in
 length. HPOMF.CLS file record 0 (the header) contains the
 15 following fields listed in Table 3:

Table 3

20	lFirstFreeEntry	Contains the record number of the first free record in HPOMF.CLS, or "0" if there are no free records.
25	FileId	Contains the null terminated string "HPOMF.CLS"
	Version	Contains the file format version number.
30	lMaxRecordNumber	Contains the number of the highest record ever allocated from within HPOMF.CLS (this highest record may or may not be free).

35
 40 Table 4, below, contains the fields for file records in
 HPOMF.CLS for file records other than file record 0:

Table 4

5	1FirstFreeEntry	Is "-1" if this record defines an installed class, otherwise this record is free and this field is the record number of the next free record, or "0" if there are no more free records. If the record is free, none of the other fields in the record is meaningful.
10		
15	ModuleFileName	Specifies the name of the application associated with objects of this class as a null-terminated string.
20	properties	Specifies the number of properties, the length of the property names and the location in HPOMF.PRP of the object's properties. See the description of HPOMF.PRP below for further definition of the structure of this field.
25		

30 In Figure 75, the relationship of HPOMF.CAT and HPOMF.CLS is shown. Within each object entry within HPOMF.CAT, the record number, which is an object's tag, serves as an identifier 650 of data files in a mass storage memory 170 associated with the object. The field "TypeInClass" serves as an identifier 651 of the class entry in HPOMF.CLS, which identifies the class of each object. Within each class entry in HPOMF.CLS, the field "ModuleFileName" serves as an identifier 652 of the application file in mass storage memory 170 which is associated with the class.

50 In Figure 76, the organization of a portion of mass storage memory 170 is shown. A root directory 660 contains pointers to an HPNWDATA directory 661 and HPNWPROG directory

5 668. HPNWPROG directory 668 is the location of storage for
applications files, represented by arrows 669. HPNWDATA
contains a plurality of HPOMFddd directories, represented by
10 directories 662, 663, 664, 665 and 666. In the HPOMFddd
directories are stored data files associated with objects.
The "ddd" in HPOMFddd stands for a three digit, leading
15 zeros, hexadecimal number. Each HPOMFddd directory has a
different "ddd" hexadecimal number. The "ddd" number
20 indicates which HPOMFddd directory stores data files for a
particular object. Data files for a particular object are
stored in the HPOMFddd directory which has a "ddd" number
25 equal to the tag for the object divided by an integer
number, e.g., fifty four. Within each HPOMFddd directory,
30 files are stored by tag numbers, e.g. data file names have
the format xxxxxxxx.lll, where "xxxxxxx" is an eight digit
leading zeros hexadecimal tag, and "lll" are a reference
35 chosen by the application.

System file 603, HPOMF.XRF is also referred to as
40 SYSXREF. This file is a list of all the links existing in
the system. It is record oriented, but does not have a
header record. Each record file is either free, or defines
45 an existing link, or is used as an overflow record from the
previous record to specify additional view specification
information. Records that contain view specifications are
50 called view specification file records. View specification
file records can be identified only by a previous record
55 which defines an existing data link; view specification file

records cannot be identified by the content within a view
specification file record. HPOMF.XRF is increased in size
16K bytes at a time. A newly allocated portion of HPOMF.XRF
is filled with zeros. File records within HPOMF.XRF which
are free or which define a link have the following fields
listed in Table 5:

Table 5

ParentTag

Contains the tag (HPOMF.CAT
record number) of the parent
object of this link. If this
field is 0, then this record
does not define a link and is
free.

ChildTag

Contains the tag of the child
object of this link. If
ParentTag in this record is 0,
and this field is also 0, then
no record beyond this record in
HPOMF.XRF defines a link.

RefName

Contains the reference name that
the parent has assigned to the
link. This field is meaningless
if ParentTag or ChildTag is
zero. Otherwise, if the top
three bits of this value are
110, the next record in the file
is a view specification.

File records within HPOMF.XRF which are view
specification file records have the following fields listed
in Table 5A:

Table 5A

5	DataId	Contains the value that the child has assigned to identify the part of itself that is being viewed through the link.
10	Snapshot	Contains the tag (HPOMF.CAT record number) of the object which is the view's snapshot, or if zero, the view has no snapshot. For further discussion of snapshots, see below.
15		
	Misc	Composed of several bit fields described below:
20		
	VS_NEWDATASET	Set if child has told OMF that new data is available, but has not been announced to the parent. The hexadecimal number 8000 0000 is a mask which indicates which bits are used for this bit field.
25		
	VS_NEWDATAANNOUNCED	Set if child has told OMF to announce new data to parent, but parent was inactive and was not notified. The hexadecimal number 4000 0000 is a mask which indicates which bits are used for this bit field.
30		
35		
	VS_SNAPSHOTOLD	Set if child has told OMF that the view's snapshot is out-of-date. The hexadecimal number 2000 0000 is a mask which indicates which bits are used for this bit field.
40		
45		
	VS_WANTMESSAGES	Set if child has told OMF that it wants to process view messages when snapshot is out-of-date. The hexadecimal number 1000 0000 is a mask which indicates which bits are used for this bit field.
50		
55		

5 10 15	VS_TEXTDISKLOC	File position in HPOMF.PRP where a view's 32 character textual data ID is located. This contains zero if no textual data ID has been defined by the child. The low order five bits of the file position are always zero and are thus not stored in the Misc field. The hexadecimal number 0FFF FFE0 is a mask which indicates which bits are used for this bit field.
20 25	VS_INITIALIZED	Set if the view specification has been initialized. If clear, all information in the view specification is zero. The hexadecimal number 0000 0010 is a mask which indicates which bits are used for this bit field.
30 35	VS_RESERVED	Reserved for future expansion. The hexadecimal number 0000 0008 is a mask which indicates which bits are used for this bit field.
40 45	VS_VIEWCLASS	Specifies the view class the child assigned to the view. The view class defines what view methods are available to the parent. The hexadecimal number 0000 0007 is a mask which indicates which bits are used for this bit field.

For example, in Figure 77, Object 671 is a folder and has a tag of "6". Object 671 is a parent of an object 672 through a link 674 and a parent of an object 673 through a link 675. Object 672 has a tag of "12". Link 674 as a reference name "1". Object 673 has a tag of "19". Link

675 has a reference name "7". Reference names are picked by
5 the parent object and need to be unique for the particular
parent object; however, other parents may have a link with
10 the same reference name provided each reference name is
unique for each parent.

Figure 79 shows a block diagram of HPOMF.XRF 603.
15 HPOMF.XRF contains an entry for each link between parents
and children. In HPOMF.XRF 603 column 731 contains the tag
of the parent for each link. Column 732 contains the tag of
20 the child for each link. Column 733 contains the reference
name for each link. The first three bit positions of column
733, shown in Figure 79 as sub-column 734, indicate whether
25 a view specification file record is present ("110") whether
no view specification file record follows ("000") or whether
30 the link is between is a link from the global parent to a
global object ("100").

35 As may be seen, entry 735 is an entry which describes
link 674 shown in Figure 77. That is, in column 731 of
entry 735 there is the parent tag "6". In column 732 there
40 is the child tag "12" and in column 733 there is the
reference name "1". Since object 671 is a folder, there is
no view, therefore the three bits within subcolumn 734 would
45 be "000".

50 Similarly, entry 736 is an entry which describes link
675 shown in Figure 77. That is, in column 731 of entry 736
there is the parent tag "6". In column 732 there is the
55 child tag "19" and in column 733 there is the reference name

5 "7". Since object 671 is a folder, there is no view,
therefore the three bits within subcolumn 734 would be
"000".

10 In Figure 78, Object 676 is a document and has a tag of
"17". Object 676 is a parent of an object 677 through a
link 679 and a parent of an object 678 through a link 680.
15 Object 677 has a tag of "8". Link 679 as a reference name
"1". Object 678 has a tag of "21". Link 680 has a
20 reference name "3".

In Figure 79, an entry 737 describes link 679 shown in
Figure 78. That is, in column 731 of entry 737 there is the
25 parent tag "17". In column 732 there is the child tag "8"
and in column 733 there is the reference name "1". Object
676 is a document, and assuming there is a view associated
30 with link 679, the three bits within subcolumn 734 contain
the three bits "110" and entry 738 is a view specification
35 record.

Similarly, an entry 739 describes link 680 shown in
Figure 78. That is, in column 731 of entry 739 there is the
40 parent tag "17". In column 732 there is the child tag "21"
and in column 733 there is the reference name "3". Assuming
45 there is a view associated with link 680, the three bits
within subcolumn 734 contain the three bits "110" and entry
740 is a view specification record.

50 In Figure 80, view specification record 740 is shown to
include a field 741 which contains a data identification for
55 the view, a field 742 which indicates whether there is a

snapshot used in the view, and a field 743 which contains
5 miscellaneous information about the view. The data
identification number is used by the child object of the
link, to determine what data is sent through the link.

10 Figures 37 - 43 show the establishment of a link with
a view. As has been discussed before, in Figure 37 window
15 791 for "Paste Up" (object 707) has been opened by double
clicking on the icon for "Paste Up". In Figure 38, using
Cursor 781, controlled by mouse 20, portion 790 of the text
20 of "Sample Text" has been selected. The portion in inverse
video stating "New Wave Office environment" is portion 790.

25 In Figure 39, cursor 781 is used to select the
selection "Share" in a pull down menu 792. Once "Share" is
selected, child object 709 ("Sample Text") creates a data
30 identification number which identifies portion 790 of the
text to child object 709. Child object 709 also causes OMF
100 to put a link to child object 709 on clipboard 720--
35 Child object 709 communicates to OMF 100 through command set
forth in Appendix B, attached hereto--. Child object 709
40 also informs OMF 100 what data identification number is
associated with the new link between the child 709 and
clipboard 720. If there is a snapshot associated with the
45 link, child 709 will also inform OMF 100 if there is a
snapshot associated with the link. Snapshots are discussed
50 more fully below. As a result OMF 100 will make an entry in
HPOMF.XRF 603 for a link between clipboard 720 and child
object 709. The view specification record for the link will
55

5 include the data identification number given to OMF 100 by
child 709.

10 In Figure 40, area 793 in window 791 is selected using
cursor 781. In Figure 41, a selection "Paste" is selected
from a pull down menu 794 using cursor 781. At this point
parent object 707 ("Paste Up") requests OMF 100 for a link
15 making him the parent of what is on clipboard 720. The view
specification record for the ^{link} between clipboard 720 and child
20 709 is copied for link 729 between parent 707 and child 709.
In Figure 43 "Sample Text" (object 709) is shown to be a
child of "Paste Up" (object 707) through link 729.

25 In Figure 42, "displayed text 790 is displayed in
"Paste Up" window 791. In accomplishing this, parent object
30 707 makes a call to OMF 100 asking that a message be sent to
the object identified by the reference name for link 729.
This message requests the child object 709 to display data
35 from this link into a location specified by parent object
707. OMF 100 takes the message from parent 707, adds the
40 data identification number from the view specification
record for link 729, and delivers the message to child 709.
Child 709 displays the data in the specified location, in
45 this case area 793. The name of the message sent from
parent 707 to OMF 100 to child 709 is "DISPLAY_VIEW",
further described in Appendix B, attached hereto.

50 Another message "PRINT_SLAVE", also described in
Appendix B, may be used when it is desired to print data on
55 a printer rather than display data on a terminal screen.

In addition, Parent 707 may send a "GET_SIZE" message
 to child object 709. In a "GET_SIZE" message, parent object
 707 identifies a reference name for link 729 and indicates
 coordinates for a display. OMF 100 takes the GET_SIZE
 message from parent 707, adds the data identification number
 from the view specification record for link 729, and
 delivers the message to child 709. Child 709 returns to
 parent 707 the size of the portion of the specified area
 that child 709 would use to display the data. This allows
 parent 707 to modify the region reserved for displaying data
 from child 709 when child 709 is not able to scale the data
 to fit in the region specified by parent 707.

When a data from a child object is being displayed by a
 parent object, and the child object changes the displayed
 data, the child objects notifies OMF 100 that there has been
 a change in the data object. For example, as described
 above, in Figure 47, data from "Star" (object 706) now
 displayed in region 795 of window 791. And, as may be seen
 in Figure 48, "Star" (object 706) is a child of "Paste Up"
 (object 707) through a link 726. Since data is being passed
 from child object 706 to parent object 707, link 726 is a
 data link which includes a view specification.

In Figure 49, the method for changing data in child
 object 706 is shown. A user places cursor 781 over region
 795 of window 791 and double clicks a button on mouse 20.
 The result is the opening and display of "Star" (object 706)
 in a window 796. Using cursor 781 to select selection

"Ellipse" in a menu window 797 results in the data within
5 "Star" (object 706) being changed from a star to an ellipse.
As shown in Figure 51, the result is a change both in data
displayed in window 796 and data displayed in region 795 of
10 window 791.

Child object 706 accomplishes this change by making a
15 call to OMF 100 stating that data associated with the data
identification number associated with link 726 is changed.
OMF 100 looks up all of the links that use the data
20 identification number. If the parent object of any of the
links is not active, OMF 100 sets the bit
VS_NEWDATAANNOUNCED for that link in HPOMF.XRF. When the
25 parent object is activated, the parent object can then
request the new data.

30 If the parent object is active, OMF 100 will send a
message to the parent object saying that new data is
available. OMF 100 will identify to the parent object the
35 reference name of the link for which there is additional
data. The parent object sends a message to the child object
40 if it wants the new data displayed. In the present case
parent object 707 is active, and has requested the new data
to be displayed in region 795 of window 791. A further
45 description of the View Specifications are found in
Appendixes B, C and D.

50 The advantage of the present invention is that parent
object 707 is able to communicate with child object 706
through OMF 100, without parent object 707 or child object
55

706 knowing the identity or any other details about each
 5 other. The parent object identifies the link using only the
 reference name of the link. The child object identifies the
 link using just the data identification number of the link.
 10 OMF 100 does all the translation and identification of which
 links and which objects are involved.

System file 604, HPOMF.PRP, is also referred to as
 15 SYSPROP. HPOMF.PRP contains all the object and class
 properties except for the fast object properties which are
 contained in HPOMF.CAT. Each record in system file 601
 20 (HPOMF.CAT) and system file 602 (HPOMF.CLS) has a properties
 field, as described above. Each properties field contains
 25 the fields described in Table 6 below:

Table 6

30	DirDiskLoc	Contains the position (byte offset) within HPOMF.PRP of the property list directory.
35	nProps	Contains the number of properties in the property list. This is the number of entries in the directory entry array described below.
40	PoolSize	Contains the combined length of all the names of the properties in the property list, including a null-terminating byte for each name. This is the size of the directory name pool described below.
45		
50		

For each object and for each class, at the DirDiskLoc
 position in the HPOMF.PRP file is the property directory for
 55 that object or that class. The directory has two major

portions: the entry array, followed by the name pool. The
 5 entry array has one entry for each property in the property
 list. Each entry has fields set out in Table 7 below:

Table 7

10	ValueLen	Specifies the length in bytes of the associated property. This can be zero.
15	ValueDiskLoc	Contains the position within HPOMF.PRP of the value of the associated property. If ValueLen is zero, this is also zero, and there is no value stored anywhere.
20	CacheOffset	This field is only used at run time and is not meaningful in the file.
25		

Immediately following the entry array is the name pool.
 This portion of HPOMF.PRP contains the null-terminated names
 30 of properties in the property list, in the same order as the
 entry array. Properties may include such things as titles,
 35 user comments, date and time of creation, the user who
 created the object, etc. For more information on
 properties, see Appendix D.

40 HPOMF.PRP grows dynamically as need. At the beginning
 of HPOMF.PRP there is a 128 byte bitmap which controls the
 45 allocation of the first 1024 pages of HPOMF.PRP. Each page
 is 32 bytes in length. These pages immediately follow the
 bit map. The bitmap is an array of words with the most
 50 significant bit of each word used first. Thus, bits 15
 through 0 of the first word of the bitmap control the
 55 allocation of pages 0 through 15 of the file, respectively.

5 When storage in the first 1024 pages is insufficient, a second bitmap is added to the file following page 1023.

10 This bitmap controls the allocation of pages 1024 through 2047, which immediately follow the second bitmap.

 Additional bitmaps and pages are added in the same way, as needed.

15 Each directory and property value is stored as a single block in the file, i.e., as a contiguous run of pages that
20 are all allocated in the same bitmap. This causes the restriction that no directory or value can exceed 32K bytes (1024 times 32) in length.

25 System file 605, HPOMF.INS, is also referred to as SYSINSTL. HPOMF.INS contains a list of the files that were
30 copied to the system when each class was installed. This information is used so that these files can be deleted when the class is de-installed.

35 The very beginning of HPOMF.INS is a double word value which serves as a validity/version identifier. In the
40 preferred embodiment the value of this double word must be 0101ABCD hex to be valid. In Table 8, this number is stored as shown because of the protocols for storage in the
45 particular processor used by the preferred embodiment, i.e. an 80286 microprocessor made by Intel Corporation.

50 Following the double word comes a series of variable length records. There is one record for each installed
55 class. The first word of each record is the length of the rest of the record, in bytes. This is followed by the null-

terminated class name of the installed class. Then follows
 5 the file names of the files copied to the OMF directories,
 each terminated by a null byte, and preceded by a byte which
 gives the length of the file name, including the length byte
 10 and the null terminator. If the file name begins with the
 special character "*", the file is assumed to be located in
 15 the HPNWPROG directory. If the file name begins with the
 special character "+" the file is assumed to be located in
 the HPNWDATA directory.

20 For example, assume two classes are installed: class
 "AB" and class "CDE". Class "AB" caused two files to be
 25 installed: "Z" to HPNWPROG directory 668 and "YY" to the
 HPNWDATA directory. Class "CDE" caused 1 file to be
 installed: "XXX" to HPNWPROG directory 668. Given this
 30 case Table 8 below shows the contents of HPOMF.INS for this
 example:

Table 8

offset	content	comments
0	CD AB 01 01	File header/version check
4	OC 00	Length of AB record (12 decimal)
6	41 42 00	"AB" + Null
9	04	Length of length byte "*"Z" + Null
A	2A 5A 00	"*Z" + Null
45 D	05	Length of length byte + "+YY" + Null
E	2B 59 59 00	"*YY" + Null
12	0A 00	Length of CDE record (10 decimal)
50 14	43 44 45 00	"CDE" + Null
18	06	Length of length byte + "*"XXX" + Null
19	2A 58 58 58 00	"*XXX" + Null

5 System File 606, HPOMF.SDF is also referred to as the
"shutdown file". HPOMF.SDF exists only when the system has
been cleanly shut down. It is deleted as the system starts,
10 and created as it shuts down. On startup, if this file is
missing, OMF assumes that the last session ended abnormally,
and so it goes through its crash recovery procedures to
15 validate and repair the system files as best it can. The
system files can be in an invalid but predictable state on a
crash. These errors are corrected without user
20 intervention. Certain other kinds of file consistency
errors are detected, but are not really possible from an
25 "ordinary" system crash. These errors are in general not
correctable and the OMF will not allow the system to come up
in this case.
30

 If HPOMF.SDF is present, it contains a list of objects.
When the system is being shut down normally, each object
35 which is active at the time can request that the OMF restart
them when the system is restarted. The list of objects,
then is the list of tags of objects which have requested
40 that they be restarted when the system is restarted.

 The first word in HPOMF.SDF is a flag word. If this
45 word is non-zero, OMF will execute its crash recovery code
even though HPOMF.SDF exists. Normal shutdown will set this
flag when producing the file if some serious error occurred
50 in the session being ended.

 After the first word, the rest of the file is a
55 sequence of three byte records. The first two bytes of each

record contain the tag of the object to be restored. The least significant byte is first. The third byte is not used in the preferred embodiment, and is zero.

For example, if the system is shut down cleanly in the last session and two objects, having tags of 2 and 7, respectively, have requested restart, the contents of HPOMF.SDF will be as set out in Table 9 below.

Table 9

offset	content	comments
0	00 00	Indicates no crash recovery needed
2	02 00	Tag of first object to restart
4	00	Unused and reserved
5	07 00	Tag of second object to restart
7	00	Unused and reserved

System file 7, HPOMFICO.NWE, is a Microsoft Windows dynamic library executable file which contains a dummy entry point and no data. Microsoft Windows is a program sold by Microsoft Corporation, having a business address at 16011 NE 36th Way, Redmond, WA 98073-9717. HPOMFICO.NWE also contains as "resources" the icons of each installed class. OMF modifies HPOMFICO.NWE directly during run time, and loads and unloads it to get the icon resources from it. The format of HPOMFICO.NWE is defined in Microsoft Windows documentation distributed by Microsoft Corporation.

Normally working with a view (see discussion on views above) causes a child's application to be invoked. Where large applications are involved, this can cause a lot of

unnecessary overhead. The use of snapshots allow this overhead to be eliminated.

5 A snapshot is an object that uses executable code from
a separate library referred to as a dynamic access library
10 (or DAL) rather than using the full application executable
code. The only data file associated with a snapshot
contains data which is to be sent from a child object to a
15 parent object. The code which encapsulates the data file
although referred to as a dynamic library, is still stored
in directory HPOMFPROG (directory 668).

20 For example, Figure 81 shows a parent object 501 linked
to a child object 502 through a link 504. Associated with
25 link 504 is a snapshot 503. Once child object has designated
snapshot 503 in a view specification record for link 504,
snapshot 503 is able to provide data from child object 502
30 to parent 501 without the necessity of invoking an
application associated with child object 502.

35 As shown in Figure 82, when there is no snapshot, child
object 502 must be active in order to send view data 522 to
parent object 501, in order for parent object 501 to display
40 view data 522 in a window display 521. In Figure 83,
however, snapshot 503 is shown to provide view data 522 to
parent object 501 without the necessity of child 502 being
45 active. Further implementation details of snapshots are
given in Appendix B, Appendix C and Appendix D.

50 Appendix A is a list of major data structures within
OMF 100.

Appendix B is a description of functions which OMF
interface 599 recognizes in the preferred embodiment of the
present invention.

Appendix C (HP NewWave Environment: Program Design
Examples) Gives examples of how the preferred embodiment of
the present invention may be implemented, including detail as
to how OMF 100 allows data to be viewed between windows
displayed on monitor 14.

Appendix D (Chapter 2 of Programmer's Guide) gives a
further overview of the preferred embodiment of the present
invention. further detail as to the operation of the
preferred embodiment of the present invention.

Claims

1. An object based distributed computer system comprising a network of workstations and means for transmitting objects between workstations characterised by objects including a first object type for storing data and a second object type for presenting data to a user, wherein objects of the second type (V-c) reference an associated object of the first type (V-s) to enable a plurality of users of workstations to access data of the object of the first type, comprising means for transmitting an object of the second type (V-c) between workstations thereby to create a reference to the associated object of the first type (V-s) for each workstation receiving an object of the second type.
2. A system according to claim 1 comprising means for copying an object of the second type (V-c) between workstations.

3. A system according to claim 1 or claim 2 wherein transmitted objects of the second type (V-c) include an identifier (60) for the associated object of the first type (V-s).
- 5 4. A system according to any preceding claim in the form of a conferencing system comprising means enabling users of the workstations to participate in a meeting over the network wherein objects of the first type (V-s) store meeting data and objects of the second type (V-c) are for presenting meeting data.
- 10 5. A method of convening a meeting using a system as claimed in claim 4 comprising transmitting an object of the second type (V-c) between workstations thereby to create a reference to the associated object of the first type (V-s) for each workstation receiving an object of the second type.
